# Negative-weight cycles

**Recall:** If a graph  $G = (V, E)$  contains a negative-weight cycle, then some shortest paths may not exist.

**Example:**

**Bellman-Ford algorithm:** Finds all shortest-path weights from a **source**  $s \in V$  to all  $v \in V$  or determines that a negative-weight cycle exists.

# Bellman-Ford algorithm

```
 $d[s] \leftarrow 0$   
for each  $v \in V - \{s\}$   
  do  $d[v] \leftarrow \infty$  } initialization
```

```
for  $i \leftarrow 1$  to  $|V| - 1$  do  
  for each edge  $(u, v) \in E$  do  
    if  $d[v] > d[u] + w(u, v)$  then } relaxation  
       $d[v] \leftarrow d[u] + w(u, v)$  } step  
       $\pi[v] \leftarrow u$ 
```

```
for each edge  $(u, v) \in E$   
  do if  $d[v] > d[u] + w(u, v)$   
    then report that a negative-weight cycle exists
```

At the end,  $d[v] = \delta(s, v)$ . Time =  $O(|V||E|)$ .

# Correctness

**Theorem.** If  $G = (V, E)$  contains no negative-weight cycles, then after the Bellman-Ford algorithm executes,  $d[v] = \delta(s, v)$  for all  $v \in V$ .

*Proof.* Let  $v \in V$  be any vertex, and consider a shortest path  $p$  from  $s$  to  $v$  with the minimum number of edges.

Since  $p$  is a shortest path, we have

$$\delta(s, v_i) = \delta(s, v_{i-1}) + w(v_{i-1}, v_i) .$$

# Correctness (continued)

Initially,  $d[v_0] = 0 = \delta(s, v_0)$ , and  $d[s]$  is unchanged by subsequent relaxations.

- After 1 pass through  $E$ , we have  $d[v_1] = \delta(s, v_1)$ .
- After 2 passes through  $E$ , we have  $d[v_2] = \delta(s, v_2)$ .
- ...
- After  $k$  passes through  $E$ , we have  $d[v_k] = \delta(s, v_k)$ .

Since  $G$  contains no negative-weight cycles,  $p$  is simple. Longest simple path has  $\leq |V| - 1$  edges.  $\square$

# Detection of negative-weight cycles

**Corollary.** If a value  $d[v]$  fails to converge after  $|V| - 1$  passes, there exists a negative-weight cycle in  $G$  reachable from  $s$ .  $\square$

# DAG shortest paths

If the graph is a *directed acyclic graph (DAG)*, we first *topologically sort* the vertices.

- Determine  $f: V \rightarrow \{1, 2, \dots, |V|\}$  such that  $(u, v) \in E \Rightarrow f(u) < f(v)$ .

# DAG shortest paths

If the graph is a *directed acyclic graph* (**DAG**), we first *topologically sort* the vertices.

- Determine  $f: V \rightarrow \{1, 2, \dots, |V|\}$  such that  $(u, v) \in E \Rightarrow f(u) < f(v)$ .
- $O(|V| + |E|)$  time

- Walk through the vertices  $u \in V$  in this order, relaxing the edges in  $Adj[u]$ , thereby obtaining the shortest paths from  $s$  in a total of  $O(|V| + |E|)$  time.

# Shortest paths

## Single-source shortest paths

- Nonnegative edge weights
  - Dijkstra's algorithm:  $O(|E| \log |V|)$
- General: Bellman-Ford:  $O(|V||E|)$
- DAG: One pass of Bellman-Ford:  $O(|V| + |E|)$

## All-pairs shortest paths

- Nonnegative edge weights
  - Dijkstra's algorithm  $|V|$  times:  $O(|V||E| \log |V|)$
- General
  - Bellman-Ford  $|V|$  times:  $O(|V|^2|E|)$
  - Floyd-Warshall:  $O(|V|^3)$

# All-pairs shortest paths

**Input:** Digraph  $G = (V, E)$ , where  $|V| = n$ , with edge-weight function  $w : E \rightarrow \mathbb{R}$ .

**Output:**  $n \times n$  matrix of shortest-path lengths  $\delta(i, j)$  for all  $i, j \in V$ .

## Algorithm #1:

- Run Bellman-Ford once from each vertex.
- Time =  $O(|V|^2|E|)$ .
- But: Dense graph  $\Rightarrow O(|V|^4)$  time.

# Floyd-Warshall algorithm

- Dynamic programming algorithm.
- Assume  $V = \{1, 2, \dots, n\}$ , and assume  $G$  is given in an **adjacency matrix**  $A = (a_{ij})_{1 \leq i, j \leq n}$  where  $a_{ij}$  is the weight of the edge from  $i$  to  $j$ .

Define  $c_{ij}^{(k)}$  = weight of a shortest path from  $i$  to  $j$  with intermediate vertices belonging to the set  $\{1, 2, \dots, k\}$ .

Thus,  $\delta(i, j) = c_{ij}^{(n)}$ . Also,  $c_{ij}^{(0)} = a_{ij}$ .

# Floyd-Warshall recurrence

$$c_{ij}^{(k)} = \min \{ c_{ij}^{(k-1)}, c_{ik}^{(k-1)} + c_{kj}^{(k-1)} \}$$

Do not use vertex k

Use vertex k

intermediate vertices in  $\{1, 2, \dots, k-1\}$

# Pseudocode for Floyd-Warshall

```
for  $k \leftarrow 1$  to  $n$  do
  for  $i \leftarrow 1$  to  $n$  do
    for  $j \leftarrow 1$  to  $n$  do
      if  $c_{ij}^{(k-1)} > c_{ik}^{(k-1)} + c_{kj}^{(k-1)}$  then
         $c_{ij}^{(k)} \leftarrow c_{ik}^{(k-1)} + c_{kj}^{(k-1)}$ 
      else
         $c_{ij}^{(k)} \leftarrow c_{ij}^{(k-1)}$ 
```

} *relaxation*

- Runs in  $\Theta(n^3)$  time and space
- Simple to code.
- Efficient in practice.

# Johnson's algorithm

1. Compute a weight function  $\hat{w}$  from  $w$  such that  $\hat{w}(u, v) \geq 0$  for all  $(u, v) \in E$ . (Or determine that a negative-weight cycle exists, and stop.)
  - Can be done in  $O(|V||E|)$  time (details skipped)
2. Run Dijkstra's algorithm from each vertex using  $\hat{w}$ .
  - Time =  $O(|V||E| \log |V|)$ .
3. Reweight each shortest-path length  $\hat{w}(p)$  to produce the shortest-path lengths  $w(p)$  of the original graph.
  - Time =  $O(|V|^2)$  (details skipped)

Total time =  $O(|V||E| \log |V|)$ .
